Rezumat

Migrarea unui clip chirurgical în calea biliară principală cu formare consecutivă de calcul reprezintă o complicație rară după colecistectomie laparoscopică, mai puțin de 100 de cazuri fiind raportate până în prezent. Prezentăm cazul unei femei de 55 de ani cu icter obstructiv prin calcul format în jurul unui clip migrat la 9 ani după colecistectomie laparoscopică. Ecografia abdominală a diagnosticat dilatarea căii biliare principale și a căilor biliare intrahepatice iar computer tomografia a indicat prezența unui clip metalic în partea distală a coledocului. Tratamentul prin colangio-pancreatografie endoscopică retrogradă (ERCP) a fost eficient iar clipul a fost recuperat folosind sonda Dormia. Mecanismul exact prin care se produce migralea clipului nu este complet înțeles dar poate fi explicat de inflamația locală și clipare ineicientă. Deși este un eveniment rar, migrarea de clip nu ar trebui exclusă în diagnosticul diferențial al pacienților cu icter sau colangită după colecistectomie laparoscopică. Tratamentul minim invaziv prin ERCP este prima opțiune de tratament pentru complicații produse de clipuri migrate dar explorarea chirurgicală a căii biliare poate fi necesară.

Cuvinte cheie: migrare de clip, icter obstructiv, ERCP, colecistectomie laparoscopică
Case Report

The case report concerns a 55-year-old caucasian woman who presented with a 5-day history of upper abdominal pain and jaundice. Nine years before she underwent laparoscopic cholecystectomy and transcystic biliary drainage followed by ERCP for biliary pancreatitis. The discharge documents noted the patient underwent cholecystectomy for chronic cholecystitis (biliary microlithiasis) during the same admission, after the pancreatitis resolved; after intraoperative cholangiography, a 6 Fr transcystic catheter was secured in place with 2 surgical clips to aid the ERCP in a rendez-vous manner. The first attempt to perform ERCP failed (failed cannulation) but succeeded 4 days after with removal of small bile duct stones. The patient had an uneventful course and was discharged with the transcystic catheter in place and returned after 14 days to have it removed after the control cholangiography.

The physical examination revealed mild pain in the right upper quadrant and icteric sclera. Laboratory blood tests results included normal leukocyte count and C reactive protein, total bilirubin of 6.7 mg/dl with direct bilirubin of 5.2 mg/dl, gamma glutamyl transpeptidase of 513 U/L, alkaline phosphatase of 215 U/L and elevated transaminases. Abdominal ultrasound described dilated extra hepatic biliary ducts. An abdominal CT scan was obtained that described a 13 mm common bile duct containing an opaque line in the distal segment – presumed to be a surgical clip.

ERCP was then performed: the previous sphincterotomy was efficient and cannulation was undemanding due to the previous apparently efficient sphincterotomy; contrast examination exposed the brown common bile duct stone concentrated around a surgical clip used during laparoscopic cholecystectomy; the calculus was retrieved using the Dormia basket. The post procedural course was uneventful and the patient was discharged after 3 days without pain, normal bilirubin and improved liver function tests.

Discussion

Migration of surgical clips after laparoscopic cholecystectomy has been reported since 1992...
To our knowledge, less than 100 cases have been reported, even though the number of laparoscopic interventions have increased worldwide (2).

Kitamura et al. presumed early on that the structures surrounding the clipped cystic duct pressed against it and led to its inversion into the lumen of the common bile duct (3) but more likely, the migration is determined by ineffective clipping that leads to leakage and chronic inflammation (2). In a similar manner, local inflammation may lead to erosion of the common bile duct wall and migration of clips; the risk is higher if clips placed on the cystic artery or cystic duct are adjacent to the common bile duct wall (4). Deans et al. suggested that cystic stump necrosis due to ischemia may facilitate migration (5). The most common complications reported so far after clip migration (obstructive jaundice, cholangitis, pancreatitis and biliary cholic) can be observed anytime between 11 days and 20 years after laparoscopic cholecystectomy (6).

Hostile environments such as schleromatous cholecystitis and biliary pancreatitis may increase even more the likelihood of poorly placed clips to migrate (7). Some studies reported that the use of absorbable clips seems to produce less complications when compared to titanium clips (8).

The peak of reported cases was between 1994 and 1998 in the early years of laparoscopic surgery for gallstone disease (6). It was advocated early on that intraoperative cholangiogram is safe and feasible for common bile duct exploration but this involves extensive dissection of the cystic duct (9,10). If the surgeon decides for transcystic biliary drainage, ligature should be used to secure the catheter in place because clip placement may put the cystic stump at risk during tube extraction. Laparoscopic ultrasound might prove useful and less invasive for detecting bile duct stones without the need for excess-
sive dissection of biliary structures (11).

The migrated clips act as a core to form gallstones by precipitation of amorphous and crystalline material (12). Most gallstones that form around migrated clips or suture material are brown, but may also be mixed containing cholesterol. The formation of brown stones is associated with infection and particularly *Escherichia coli* (12).

ERCP is considered to be the procedure of choice for retrieving common bile duct migrated clips, with a success rate of 84.5% (6). If for different reasons ERCP fails or can’t be performed due to altered anatomy or previous gastrointestinal tract surgery, percutaneous transhepatic management may be attempted, otherwise surgical common bile duct exploration is warranted (13,14).

Our opinion is that in the presented case, clip migration started once the transcystic catheter was removed. Being secured in place by 2 clips, after removal of the catheter, the cystic stump was left ineffectively closed but the sphincterotomy prevented bile leakage. The operative setting, after resolution of biliary pancreatitis and 2 ERCP attempts also acted as cofactors. But why the clip did not pass into the duodenum through a presumably wide papilla is difficult to understand.

**Conclusion**

In summary, clip migration is an unusual complication after laparoscopic cholecystectomy. This report illustrates the minimally invasive management of obstructive jaundice due to clip migration 9 years after laparoscopic cholecystectomy.
